Workshop: Dealing with Data in R

Loading & Cleaning Data in R

I know the file exists, why doesn't R?

1

First things first

- Save previous script
- Open New File

 (make sure you're in the RStudio Project)
- Write library(tidyverse) at the top
- Save this new script

 (consider names like cleaning.R or 3_loading_and_cleaning.R)

Side Note

R base vs. tidyverse

R base vs. tidyverse

R base

- Basic R
- Packages are installed and loaded by default
- Base pipe |> *

tidyverse

- Collection of 'new' packages developed by a team closely affiliated with RStudio
 - e.g., ggplot2, dplyr, tidyr, readr
 - Packages designed to work well together
- Use a slightly different syntax
- tidyverse pipe %>% or base pipe |> *

Useful to know if functions are tidyverse or R base

Dealing with data

1. Loading data

• Get your data into R

2. Looking for problems

- Typos
- Incorrectly loaded data

3. Fixing problems

- Corrections
- Renaming

4. Setting formats

- Dates
- Numbers
- Factors

5. Saving your data

Loading Data

Data types: What kind of data do you have?

Specific program files

Туре	Extension	R Package	R function
Excel	.xls, .xlsx	readxl*	read_excel()
Open Document	.ods	readODS	read_ods()
SPSS	.sav, .zsav, .por	haven	read_spss()
SAS	.sas7bdat	haven	read_sas()
Stata	.dta	haven	read_dta()
Database Files	.dbf	foreign	read.dbf()

Convenient but...

- Can be unreliable
- Can take longer

For files that don't change, better to save as a * . csv

Data types: What kind of data do you have?

General text files

Туре	R base	readr package *
Comma separated	read.csv()	<pre>read_csv(), read_csv2()</pre>
Tab separated	read.delim()	read_tsv()
Space separated	read.table()	read_table()
Fixed-width	read.fwf()	read_fwf()

- readr package especially useful for big data sets (fast!)
- Error/warnings from readr are a bit more helpful

We'll focus on

Common error

```
1 my_data <- read_csv("weather.csv")
Error: 'weather.csv' does not exist in current working directory ('/home/steffi/Projects/Workshops/workshop-dealing-with-data').</pre>
```

With no folder (just file name) R expects file to be in Working directory

Working directory is:

- Where your RStudio project is
- Your home directory (My Documents, etc.) [If not using RStudio Projects]
- Where you've set it (using setwd() or RStudio's Session > Set Working Directory)

A note on file paths (file locations)

1 /home

- folders separated by /
- home is a folder

A note on file paths (file locations)

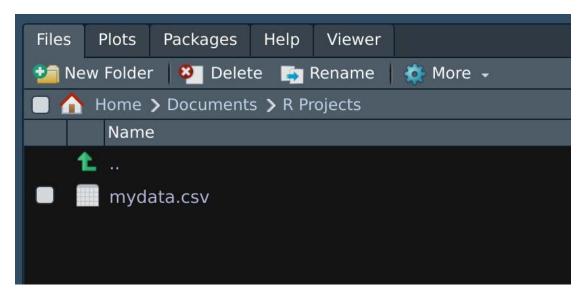

```
1 /home/steffi/
```

- folders separated by /
- home and steffi are folders
- steffi is a folder inside of home

A note on file paths (file locations)

```
1 /home/steffi/Documents/R Projects/mydata.csv
```

- folders separated by /
- home, steffi, Documents, R Projects are folders
- steffi is inside of home, Documents is inside of steffi, etc.
- mydata.csv is a data file inside R Projects folder

RStudio Files Pane

Absolute Paths

OS	Path
LINUX	/home/steffi/Documents/R Projects/mydata.csv
WINDOWS	C:/Users/steffi/My Documents/R Projects/mydata.csv
MAC	/users/steffi/Documents/R Projects/mydata.csv

Relative Paths

Path	Where to look
mydata.csv	Here (current directory)
/mydata.csv	Go up one directory (/)
data/mydata.csv	Stay here, go into "data" folder (data/)
/data/mydata.csv	Go up one directory (/), then into "data" folder (data/)

Full location, folders and filename

Only *relative* info
Use relative symbols (e.g.,
. . /)

Keep yourself organized

For simple projects

- Create an 'RStudio Project' for each Project
- Create a specific "data" folder within each project (one per project)

```
- Prospect Lake Quality # Project Folder
- prospect_analysis.R
- data # Data Folder
- prospect_data_2017-01-01.csv
- prospect_data_2017-02-01.csv
```

• Use **relative** paths to refer to this folder

```
1 d <- read_csv("data/prospect_data_2017-01-01.csv")
```

Let's Load Some Data!

Your turn: Load some data

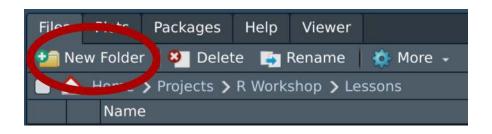

- 1. Create a 'data' folder in your RStudio project
- 2. Put rivers_correct.xlsx file in the "data" folder
- 3. Load the package

```
1 library(readxl)
```

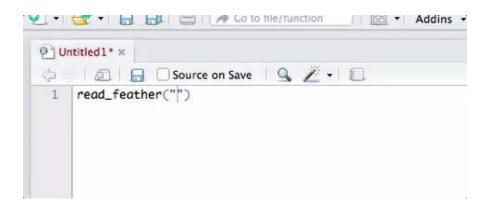

4. Read in the Excel file and assign to object rivers

```
1 rivers <- read_excel("data/rivers_correct.xlsx")</pre>
```

- 5. Use head() and tail() functions to look at the data e.g., head(rivers) and tail(rivers)
- 6. Click on the rivers object in your "Environment" pane to look at the whole data set

Click on "New Folder"

Use the 'tab' key in RStudio when typing in the file name for auto-complete

Your turn: Load some data

```
1 library(readxl)
2 rivers <- read_excel("data/rivers_correct.xlsx")</pre>
```

```
1 head(rivers)
# A tibble: 6 \times 7

How do I know which function to use?

Program-specific files

- Files which only normally open in a particular program (e.g., Excel)
- Load with function from specific package (e.g. read_excel from readxl package)

Text files

- Files which open in notepad
- Files which open in RStudio when you click on them in the Files Pane
- Load with function from readr package (e.g. read_csv(), read_tsv(), etc.)

Look at the file extension:

- rivers_correct.xlsx → Excel file → read_excel()
- rivers_raw.csv → Comma-separated-variables → read_csv()

But sometimes not clear...

How do I know which function to use?

Look at the file: master_moch.txt

- Put this file in your **data** folder
- In lower right-hand pane, click on **Files**
 - Click on data folder
 - Click on master_moch.txt
 - Click "View File" (if asked)

```
ID region hab freq
                        freq.sd p.notes
                            3.9806600009
MCB02
        kam 0.5266879074
                                             3.9806600009
                                                             0.4592592593
MCB03
        kam - 0.9707703735
                           4.1090031783
                                             4.1090031783
                                                             0.5
        kam - 0.9707703735
                           4.2463067674
                                                             0.5151515152
MCB04
                                             4.2463067674
```

This **does not** read the file into R, but only shows you the contents as text.

How do I know which function to use?

Peak:

- Pick a read function with your best guess (read_csv() is a good start)
- Use n_max to read only first few rows

```
1 read_csv("data/master_moch.txt", n_max = 3)

# A tibble: 3 × 1
   `ID\tregion\thab\tfreq\tfreq.sd\tp.notes`
   <chr>
1 "MCB02\tkam\t0.5266879074\t3.9806600009\t3.9806600009\t0.4592592593"
2 "MCB03\tkam\t-0.9707703735\t4.1090031783\t4.1090031783\t0.5"
3 "MCB04\tkam\t-0.9707703735\t4.2463067674\t4.2463067674\t0.515151515152"
```

\t means tab, so this is tab-separated data

How do I know what to use?

Peak:

Try again with read_tsv()

Excellent!

Specifics of loading functions

col_names

• Geolocator data

```
1 my data <- read csv("data/geolocators.csv")</pre>
          2 my data
# A tibble: 20 \times 2
   `02/05/11 22:29:59` `64`
   <chr>
                        <dbl>
 1 02/05/11 22:31:59
                           64
 2 02/05/11 22:33:59
                           38
                           38
 3 02/05/11 22:35:59
 4 02/05/11 22:37:59
                           34
 5 02/05/11 22:39:59
                           30
 6 02/05/11 22:41:59
                           34
 7 02/05/11 22:43:59
                           40
 8 02/05/11 22:45:59
                           46
 9 02/05/11 22:47:59
                           48
10 02/05/11 22:49:59
                           46
# i 10 more rows
```

- read_csv, read_tsv, etc. assume that the first row contains the column names
- This file doesn't have headers

Oops?

col_names

Geolocator data

Declare no headings

```
1 my data <- read csv("data/geolocators.csv",</pre>
                                  col names = FALSE)
          3 my_data

Your turn: Load this data set

Load the telemetry data set: Sta A Data 2006-11-07.dmp

- 1. Look at the file
- 2. Decide which R function to use based on delimiter (comma, space, or tab?)
- 3. Any other options need to be specified?

It should look like this:

# A tik	oble: 19 × 7					
Start	tDate Time	Frequency	`Rate/Temp`	Pwr Ant	SD	
<	<dbl> <time></time></dbl>	<dbl></dbl>	<dbl></dbl>	<dbl> <chr></chr></dbl>	<dbl></dbl>	
1 3	39022 17:15:36	150.	34.8	175 M0	0	
2 3	39022 17:19:14	148.	19.2	72 M0	0	
3 3	39022 17:19:25	148.	19.7	194 M1	0	
4 3	39022 17:20:04	149.	33.8	104 MO	0	
5 3	39022 17:20:17	149.	33.7	152 M1	0	
6 3	39022 17:20:57	150.	34.2	188 MO	0	
7 3	39022 17:22:50	148.	9.8	188 MO	0	
# i 12	more rows					Too Easy?

Load some of your own tricky data

Your turn: Load this data set

Load the telemetry data set: Sta A Data 2006-11-07.dmp

```

# i 12 more rows
```

Your turn: Load this data set

Too Easy?

- Use sheet argument to access specific sheet (excel_sheets() lists them all)
- skip the first *three* rows (including the headers)
- provide new header names

```
1 excel sheets("data/rivers correct.xlsx") # Or look yourself;)
                 "Oswegatchie"
[1] "Sheet1"
         1 read excel("data/rivers correct.xlsx", sheet = "Oswegatchie", skip = 3,
                      col names = c("name", "site", "element", "amount",
                                    "temp", "year", "weather"))
# A tibble: 75 \times 7
                        element amount
              site
                                          temp year weather
  name
              <chr>
                                  <dbl> <dbl> <dbl> <chr>
  <chr>
                         <chr>

Looking for problems

Look at the data

- Make sure columns as expected (correctly assigned file format)
- Make sure no extra lines above the data (should we have used a skip?)
- Make sure column names look appropriate

```

                                                                                        2009
```

count () categories

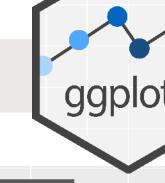

count() is from dplyr*

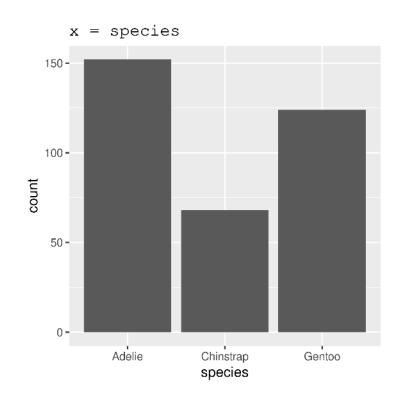

- Check for sample sizes and potential typos in categorical columns
- Assess missing values

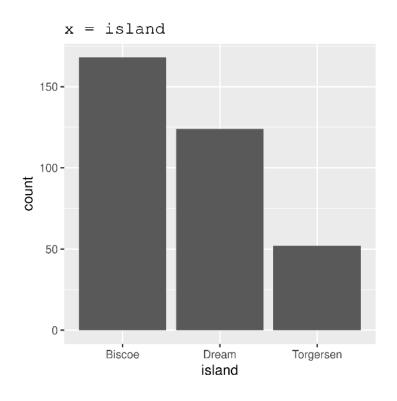

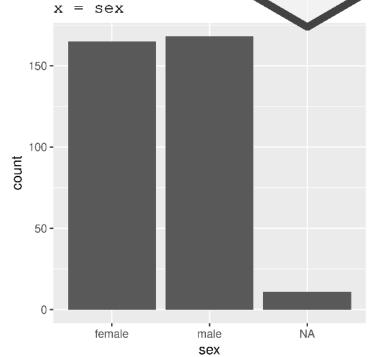

Plot categories

```
1 # Replace COLUMN with the column name to explore
2 ggplot(data = penguins, aes(x = COLUMN)) +
3 geom_bar()
```

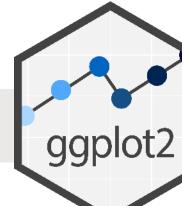

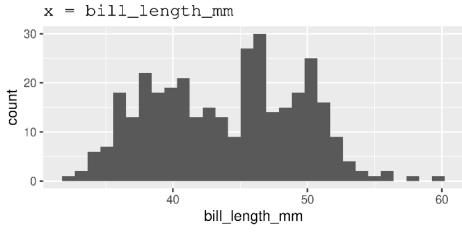

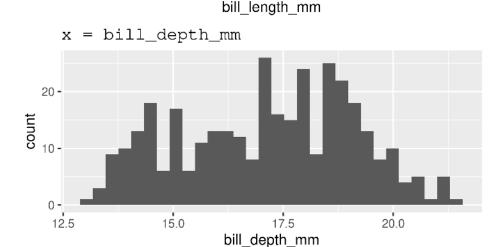

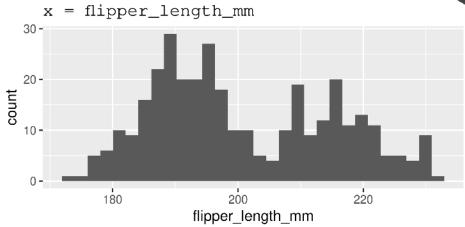

Plot numbers

```
# Replace COLUMN with the column name to explore
ggplot(data = penguins, aes(x = COLUMN)) +
geom_histogram()
```

Example of problematic data

rivers_raw.csv

```

- Column names are not R-friendly (River Name and Temperature C°) or obvious (what is Ele?)
- At least one typo in River (Grase should be Grasse)

                                 0.681
                                                    2023
# i 290 more rows
```

Remember the typos...

Replace typos

Combine the if_else function with the mutate() function

```
1 rivers <- mutate(rivers, river_name = if_else(river_name == "Grase", "Grasse", river_name))</pre>
```

Check that it's gone:

if_else() and mutate() from dplyr package*

mutate() creates or changes columns in a data frame:

```
1 mutate(dataframe, column = new_values)
```

if_else() tests for a condition, and returns one value if FALSE and another if TRUE

```
1 if_else(condition, value_if_true, value_if_false)
```

Iterative process

- Make some corrections
- Check the data
- Make some more corrections (either add to or modify existing code)

Many corrections?

Try case_when() from dplyr package*

case_when() tests for multiple conditions, and returns different values depending

```
case_when(condition1 ~ value_if_true1,
condition2 ~ value_if_true2,
condition3 ~ value_if_true3,
TRUE ~ default_value)
```

Your Turn: Fix another "Grasse" typo

- 1. Check the data with count ()
- 2. Use mutate() and if_else() to fix the typo

```
rivers <- read_csv("data/rivers_raw.csv")
rivers <- clean_names(rivers)
rivers <- rename(rivers, element = ele, amount = amo, temperature = temperature_c)
rivers <- select(rivers, -wea)
rivers <- mutate(rivers, river_name = if_else(river_name == "Grase", "Grasse", river_name))
rivers <- mutate(???, ??? = ???)</pre>
```

Too Easy?

Examine and fix problems in your own data

Your Turn: Fix another "Grasse" typo

- 1. Check the data with count ()
- 2. Use mutate() and if_else() to fix the typo

```
rivers <- read_csv("data/rivers_raw.csv")
rivers <- clean_names(rivers)
rivers <- rename(rivers, element = ele, amount = amo, temperature = temperature_c)
rivers <- select(rivers, -wea)
rivers <- mutate(rivers, river_name = if_else(river_name == "Grase", "Grasse", river_name))
rivers <- mutate(rivers, river_name = if_else(river_name == "grasse", "Grasse", river_name))</pre>
```

To be more efficient, fix all typos at once

```
1 rivers <- read_csv("data/rivers_raw.csv")
2 rivers <- clean_names(rivers)
3 rivers <- rename(rivers, element = ele, amount = amo, temperature = temperature_c)
4 rivers <- select(rivers, -wea)
5 rivers <- mutate(rivers,
6 river_name = if_else(river_name %in% c("Grase", "grasse"), "Grasse", river_name))</pre>
```

== compares one item to one other %in% compares one item to many different ones

One last typo to fix

```
rivers <- read_csv("data/rivers_raw.csv")
rivers <- clean_names(rivers)
rivers <- rename(rivers, element = ele, amount = amo, temperature = temperature_c)
rivers <- select(rivers, -wea)
rivers <- mutate(rivers,
river_name = if_else(river_name %in% c("Grase", "grasse"), "Grasse", river_name),
river_name = if_else(river_name == "raquette", "Raquette", river_name))</pre>
```

Combine with case_when()

```
rivers <- read_csv("data/rivers_raw.csv")
rivers <- clean_names(rivers)
rivers <- rename(rivers, element = ele, amount = amo, temperature = temperature_c)
rivers <- select(rivers, -wea)
rivers <- mutate(rivers,
river_name = case_when(river_name %in% c("Grase", "grasse") ~ "Grasse",
river_name == "raquette" ~ "Raquette",
river_name == "raquette" ~ "Raquette",
river_name)</pre>
```

Tangent: tidyverse functions

tidyverse functions

rename(), select(), mutate()

- tidyverse functions always start with the data, followed by other arguments
- you can reference any column from 'data'

```
rivers <- read_csv("data/rivers_raw.csv")
rivers <- clean_names(rivers)
rivers <- rename(rivers, element = ele, amount = amo, temperature = temperature_c)
rivers <- select(rivers, -wea)
rivers <- mutate(rivers, river_name = if_else(river_name %in% c("Grase", "grasse"), "Grasse", river_name))</pre>
```

- rename() changes column names
- select() chooses columns to keep or to remove (with -)
- mutate() changes column contents

Why use tidyverse functions?

Pipes! | >* Allow you to string commands together

Instead of:

We have:

```
rivers <- read_csv("data/rivers_raw.csv") |>
clean_names() |>
rename(element = ele, amount = amo, temperature = temperature_c) |>
select(-wea) |>
mutate(river_name = case_when(river_name %in% c("Grase", "grasse") ~ "Grasse",
river_name == "raquette" ~ "Raquette",
TRUE ~ river_name))
```

Play around

Take a moment to play with this code in your console

Convert this:

To this:

```
rivers <- read_csv("data/rivers_raw.csv") |>
clean_names() |>
rename(element = ele, amount = amo, temperature = temperature_c) |>
select(-wea) |>
mutate(river_name = case_when(river_name %in% c("Grase", "grasse") ~ "Grasse",
river_name == "raquette" ~ "Raquette",
TRUE ~ river_name))
```

Dealing with NAs

Data that *is* missing Data that *should* be missing

Exploring NAs

- We saw missing values in amount
- Use filter() to take a closer look

```
1 filter(rivers, is.na(amount))
# A tibble: 39 \times 6
  river name site element amount temperature year
  <chr>
            <chr>
                  <chr>
                               <dbl>
                                         <dbl> <dbl>
1 Raquette Down stream Al
                                 NA

            Down stream Gd
                                 NA
# i 29 more rows
```

Omitting NAs

drop_na() is from tidyr*

Omit NAs from the amount column only (drop those rows)

```
1 rivers_no_na <- drop_na(rivers, amount)</pre>
```

Omit **all** NAs from **all** columns (drop those rows)

```
1 rivers no na <- drop na(rivers)</pre>
```

Check...

Side Note: filter() also omits NAs 😱

If we filter by the column with NAs, they are silently dropped

```
1 filter(rivers, amount < 0.05)</pre>
# A tibble: 15 \times 6
  river name site
                       element amount temperature year
  <chr>
                       <chr>

Replacing NAs

replace_na() is from tidyr*

```
1 rivers_no_na <- mutate(rivers, amount = replace_na(amount, 0))</pre>
```

Check...

No more NAs!

(If you want to do a more complex replacement, you'll have same intim bee (o) for was e_when() like we did for typos.)

Converting to NA

Remember the problem with temperature?

na_if() is from dplyr*

```
1 rivers <- mutate(rivers, temperature = na_if(temperature, -99))</pre>
```

Check...

Fixing formats

Changing classes

Function	Input	Output
as.character()	Any vector	Text (Characters)
as.numeric()	Any vector (but returns NAs if not numbers)	Numbers
as.logical()	TRUE, FALSE, T, F, 0 (FALSE), any other number (all TRUE)	TRUE or FALSE
as.factor()	Any vector	Categories

Your turn, try the following. We'll deal with dates and times later...

```
1 a <- c("hi", "hello", "bonjour")</pre>
                                                                  1 b <- c(1, 0, 20)
1 as.character(a)
                                                                  1 as.character(b)
2 as.numeric(a)
                                                                  2 as.numeric(b)
3 as.logical(a)
                                                                  3 as.logical(b)
4 as.factor(a)
                                                                  4 as.factor(b)
```

Changing classes

Your turn, try the following...

```
1 b <- c(1, 0, 20)
         1 a <- c("hi", "hello", "bonjour")</pre>
         1 as.character(a)
                                                                      1 as.character(b)
                                                             [1] "1" "0" "20"
[1] "hi" "hello" "bonjour"
         1 as.numeric(a)
                                                                      1 as.numeric(b)
[1] NA NA NA
                                                             [1] 1 0 20
         1 as.logical(a)
                                                                      1 as.logical(b)
[1] NA NA NA
                                                             [1] TRUE FALSE TRUE
         1 as.factor(a)
                                                                      1 as.factor(b)
      hello bonjour
[1] hi
                                                             [1] 1 0 20
Levels: bonjour hello hi
                                                            Levels: 0 1 20

Put it all together...

And you have a clean, corrected data frame ready to use

- You have not changed the original data
- You have a **reproducible** record of all corrections
- You can alter these corrections at any time
- You have formatted your data for use in R
- Read these steps line by line to remind yourself what you did

Put it all together...

Feel free to annotate within a pipe

```
1 rivers <- read csv("data/rivers raw.csv") |>
 2 # Fix column names
 3 clean names() |>
4 rename(element = ele, amount = amo, temperature = temperature c) |>
 5 select(-wea) |>
6 mutate(
    # Correct typos
       river name = case when (river name %in% c("Grase", "grasse") ~ "Grasse",
                             river name == "raquette" ~ "Raquette",
                             TRUE ~ river name),
11
       # Missing amounts should be 0
       amount = replace na(amount, 0),
       # Problems with temperature logger, -99 is a mistake
       temperature = na if(temperature, -99),
14
       # Convert for plotting
      year = factor(year))
```

Dates and Times

(Or why does R hate me?)

Dates and Times

- Date/times aren't always recognized as date/times
- Geolocator data

```
1 geolocators <- read csv("data/geolocators.csv", col names = c("time", "light"))</pre>
          2 geolocators
# A tibble: 21 \times 2
  time
                     light
  <chr>
                     <dbl>
1 02/05/11 22:29:59
                        64
                        64
2 02/05/11 22:31:59
3 02/05/11 22:33:59
4 02/05/11 22:35:59
                        38
5 02/05/11 22:37:59
6 02/05/11 22:39:59
                        30
# i 15 more rows
```

Here time column is considered chr (character/text)

You may know it's a date, but R does not

lubridate package *

- Part of tidyverse, but needs to be loaded separately
- Great for converting date/times (i.e. telling R this is a date/time)

```
1 library(lubridate)
          2 geolocators <- mutate(geolocators, time fixed = dmy hms(time))</pre>
          3 geolocators
# A tibble: 21 \times 3
  time
                    light time fixed
                    <dbl> <dttm>
  <chr>
1 02/05/11 22:29:59
                       64 2011-05-02 22:29:59
2 02/05/11 22:31:59
                      64 2011-05-02 22:31:59
3 02/05/11 22:33:59
                      38 2011-05-02 22:33:59
4 02/05/11 22:35:59 38 2011-05-02 22:35:59
5 02/05/11 22:37:59
                      34 2011-05-02 22:37:59
6 02/05/11 22:39:59
                       30 2011-05-02 22:39:59
# i 15 more rows
```

Now time_fixed column is considered dttm (Date/Time)

So You know it's a Date/Time and now R knows too

lubridate package *

Generally, only the order of the year, month, day, hour, minute, or second matters.

For example

date/time format	function	output class
2018-01-01 13:09:11	<pre>ymd_hms()</pre>	dttm (POSIXct/POSIXt)
12/20/2019 10:00 PM	<pre>mdy_hm()</pre>	dttm (POSIXct/POSIXt)
31/01/2000 10 AM	dmy_h()	dttm (POSIXct/POSIXt)
31-01/2000	dmy()	Date

lubridate is smart enough to detect AMs and PMs

Saving data

(For the love of all that is good don't *lose* that data!!!)*

* but if you've been paying attention, you know that you only need the script 😉

Saving data

Keep yourself organized

- Keep your R-created data in a **different** folder from your 'raw' data *
- If you have a lot going on, split your work into several scripts, and number the both the scripts AND the data sets produced:
- 1_cleaned.csv
- 2_summarized.csv
- 3_graphing.csv

Save your data to file:

```
1 write_csv(rivers, "datasets/rivers_cleaned.csv")
```

Dealing with data

1. Loading data

• Get your data into R

2. Looking for problems

- Typos
- Incorrectly loaded data

3. Fixing problems

- Corrections
- Renaming

4. Setting formats

- Dates
- Numbers
- Factors

5. Saving your data

Wrapping up: Common mistakes

Assuming your data is in one format when it's not

- Print your data to the console and use **skim()** to explore the format of your data
- Use skim(), count(), filter(), select(), ggplot() to explore the content of your data

Wrapping up: Common mistakes

Confusing pipes with function arguments

Pipes (|> or %>%) pass the output from one function as input to the next function:

• Arguments may be on different lines, but all part of *one* function

Wrapping up: Further reading
